Title:

Comments: I don't see the importance of this project as no sediment issues have been determined in the project outline and all the effects it could have on larger enhancement projects with salmon/trout. Also if huckleberries are a main idea to clear cut an area does not make sense? If huckleberries are the main idea for this project, it should be directed towards logging land owners to plant huckleberry plants when replanting a clear-cut area. If pests are the another potential issue, monitor the forests, cut infected ones down. As for benefiting pollinators are you talking in regards to squirrels,birds,bugs,bears,elk,cougars you name it? Every life in the forests are natural pollinators, but taking their habitat away due to stress caused by humans will not allow those places to thrive and continue to be pollinated. Let the area rest from the past trauma it has already been through, old trees will eventually blow down with wind, allowing the next plant to take it's place. As well as other great forest berries that have already been established naturally, and are great resources for all pollinators.
