The word resiliency should be used properly. it is not. we have searing heat and only hardy invasive species will survive after the proposed thinning and burning occur. i resent use of the word restoration. i witnessed this past july backpacking how resilient and restorative the most welcome rains were in the high country. the high country depends on the ground cover of the lower elevations to function. a complete analysis from assorted independent studies is needed site specific to the landscape area involved. an EIS is without question needed that covid is not taken into account, nor climate disruption is unbelievable. only fear of fires, which need to happen and they move fast unlike prescribed burns which shoulder and are much more damaging. just do an EIS with on FS employees
