Comments:

A 2020 scientific study shows that ecological damage in the High Uintas as a result of domestic sheep grazing is severe, and vegetation productivity is even lower today than it was in the 1960s. In addition, domestic sheep are driven into alpine habitats occupied by bighorn sheep, amplifying the likelihood that wild bighorns will contract deadly livestock diseases that could wipe out the entire bighorn sheep population in the Uinta Mountains.

Existing domestic sheep grazing that is severely damaging the fragile alpine meadows of the High Uintas Wilderness and threatens the survival of the native bighorn sheep is an unacceptable use of these sensitive public lands.

Existing domestic sheep grazing that is severely damaging the fragile alpine meadows of the High Uintas Wilderness and threatens the survival of the native bighorn sheep is an unacceptable use of these sensitive public lands.

It's time to adopt Alternative 1, the Environmentally Preferred Alternative, which would end domestic sheep grazing in the High Uintas.
