Comments: Research (attached) demonstrates the profound impacts of domestic sheep overgrazing in the High Uintas. The study revealed that damage so severe that vegetation productivity is even lower today than it was in the 1960s. Too many sheep on these lands puts our bighorn sheep populations at risk for disease and that's not something that we should take lightly. I trust in the US Forest Service to make decisions based on science, not on desires of any groups or individuals who use the land. Thank you for allowing input on this important matter that is creating devastating impacts to our public lands, the wildlife that inhabit it, and the public who use it.
