Comments: The health of all Montana forest's are in pore health do to lack of forest management most have excessive fire load and dead or dieing trees in them this has caused extreme fires which destroy all habitat for animals and people and can take 20 to 30 years to start growing back this is not good for everyone we need to thin out and in increase space between trees to promote heath growth and reduce ladder fuel's so it don't wipe out the hole forest most of the old growth I have been in and thinned I have found a lot of rot in them this tells me that they are not healthy most likely because they are struggling for resources and their is to many trees in one area at the rate fires are going if we don't start doing something now all we will have is black forest and no habitat
